

ASSET MANAGEMENT ADVICE SYSTEM AND RECORDING MEDIUM
CONTAINING PROGRAM OF THE SYSTEM

FIELD OF THE INVENTION

The present invention relates to a data processing system for asset management through the use of securities, foreign exchange, futures or the like, and in particular, to an art of net trade utilizing a data communications network such as the Internet.

BACKGROUND OF THE INVENTION

Under the recent development of the information industry, electronic commerce utilizing a data communications network such as the Internet has been brisk. Net trade through data communications has enabled us to make transactions from personal computers at home, including transactions of assets such as securities represented by stocks and bonds, foreign exchange, and commodities futures relating to noble metals, natural resources and agricultural products.

Such an existing asset management system utilizing net trade is only a data-presenting means providing materials for judgement, in which a trading agent such as a securities company manages data such as stock prices and trading volume to provide it in the form of charts, tables or the like to a user terminal, and the user refers to it to make judgements by himself and orders trading. It is predictable that with the prevalence of personal computers and data communications, nonprofessionals with a little knowledge will be able to make asset transactions such as stock investments easily at home. However, through the conventional data-presenting means only, nonprofessionals can not easily perform asset management.

SUMMARY OF THE INVENTION

The present invention provides a system in which a user can make transactions while receiving advice on asset

09630834 080200

management as if he is served by a professional adviser at the window, instead of providing the conventional means merely representing data. Specifically, the present invention provides an asset management advice system comprising a data base that stores purchase and sale signals relating to an asset to be traded and a data processing means that produces a suitable investment scenario (calling an investment judgement program) when user's property information (constraints such as user's preference with respect to asset management and funds) is input from a user terminal (such as a personal computer, cellular phone or game terminal) via a predetermined communication means, refers to the purchase and sale signals to send management advice data based on the investment scenario to the user terminal, and makes an asset transaction in accordance with a response to the management advice data from the user terminal. Alternatively, the present invention provides an asset management advice system comprising a communication means connected to a data base that stores purchase and sale signals relating to an asset to be traded and a data processing means that produces a suitable investment scenario when user's property information is input from a predetermined input means, refers to the purchase and sale signals to provide management advice data based on the investment scenario to the user, and makes an asset transaction in accordance with user's response to the management advice data. The former is a system in which a host on the side of an asset trading agent such as a securities company or an investment advisory company serves as the data processing means to make an asset transaction. The latter is a system in which a personal computer a user owns serves as the data processing means to make an asset transaction, while the data base is managed on the side of the agent.

0022030"4E30E950

The purchase and sale signals may be those that are calculated on the ground of data such as prices (such as stock prices, foreign exchange and commodities-futures prices), the amounts of remains (such as the amount of issuance of securities and the amount of existence of commodities) and the volume of business (such as trading volume and the amount of purchase and sale) of assets to be traded, and also optimized by a prescribed calculation expression for the data base. Further, quantitative data relating to assets to be traded and their sources (such as the source of issuance of securities and the source of supply of commodities) and qualitative data relating to assets to be traded and their sources can also be utilized as ground for the purchase and sale signals. Furthermore, quantitative macro information data in the locations of the sources and the regions of transactions of assets to be traded and qualitative macro information data in the locations of the sources and the regions of transactions of assets to be traded can also be utilized. The quantitative data corresponds, when the assets are, for example, securities such as stocks and bonds, to figures included in profit-and-loss statements, financial statements and the like of the issuing companies, and when the assets are noble metals, natural resources, agricultural products and the like, to figures of the amount of production, the amount of consumption and the like. The qualitative data corresponds, when the assets are, for example, securities, to information of the issuing companies comprising credit information such as the industries they belong, the stock markets on which their stocks are listed, the status of the over-the-counter registration, the grading by a grading institution, relations with a financial institution in business connections and the status of bills circulation, finance information such as securities planned to be newly issued, capital increase and stock divisions, information

00280"480E960

relating to the managers such as change of the managers and reshuffle of the executive establishments, management information such as reorganization of business, restructuring, a merger or joint with another company, a buyout of another company, an acquisition by another company or a tie-up with another company, and information relating to the management resources such as development and sales of new products or discovery of a new vein. The quantitative macro information data corresponds to economic statistics data such as the rate of economic growth, the rate of price increase and the unemployment rate, and the qualitative macro information data corresponds to the political situation and the social situation.

It is preferable that a data processing means in this system automatically collect data concerning purchase and sale signals relating to an asset recommended by an investment scenario and data constituting grounds for them to update a data base. Specifically, the update of the data base is preferably not started by a user with some switch but made by the data processing means automatically obtaining data from media such as a news agency and an exchange, so that user's load such as remembering to update the data base is lightened and the update can be made periodically, for example, one time a day unfailingly. As a result, management advice data referring to the up-to-date purchase and sale signals can always be produced. Further, the automatic update system allows update in real time of that kind of data for which earlier update is required. Furthermore, the data processing means can be set to automatically collect data concerning purchase and sale signals relating to user's holding assets and data constituting grounds for them to update the data base.

The asset management advice system of the present invention also makes the data processing means produce a plurality of investment scenarios with different

0022080" 4E80E966

characteristics (calling a plurality of investment judgement programs) and produce management advice data based on one investment scenario of them in accordance with user's selection. Specifically, the range of selection can be widened and it becomes possible to select an investment scenario characterized in a high-risk, high-return type or to select an investment scenario characterized in a risk-avoiding type according to circumstances. In this case, it is recommendable that an animation character be set for each investment scenario and the character operates in accordance with management advice data to be an interface with a user. This proceeds the management in an interactive manner as if the animation character is an advisor at the store and enables a nonprofessional of asset management easy to handle it. The character recommends an asset to be traded in accordance with the management advice data, and the user receiving it makes purchase and sale. Alternatively, the character gives comments on an asset the user is going to purchase or sell in his judgement. Further, according to circumstances, the user entrusts effecting a transaction to the character and the character reports the result of the transaction to the user. The user thus proceeds the transaction, receiving advice from the character, however, he does not always need to follow the advice.

Under this animation character scheme, the data processing means may store management performance records for a past prescribed period of each investment scenario and present the management performance records as well as the animation character to a user. This allows the user to monitor management performances for e.g. the past ten years of each character to objectively judge the characteristics of the character.

In the case where such a plurality of investment scenarios are produced, it is recommendable to set the data

09630834 080200

It is preferable that the user can select either the real mode in which to access the market to actually perform an asset transaction made by the data processing means in accordance with a response from the user or the virtual mode in which not to access the market to perform it virtually. In the real mode, it works as an actual net trade and purchase and sale are actually ordered and there occur profit and loss in reality. In the virtual mode, there is no actual order and no profit and loss occur in reality. In brief, in the virtual mode, it works as a kind of simulation (game).

The present invention also provides, as a medium of a program realizing the above-described system, a recording medium recording an asset management advice program that makes a data processing unit perform a scenario producing process of producing a suitable investment scenario when user's property information is input, a management advising process of producing management advice data based on the investment scenario, referring to purchase and sale signals relating to an asset to be traded stored in a data base, and a trading process of performing an asset transaction in accordance with user's response to the management advice data. The asset management advice program can further include a process in which the data processing unit automatically collects data concerning purchase and sale signals relating to an asset recommended by an investment scenario and data constituting grounds for them to update the data base. In addition, a process of automatically collecting data concerning purchase and sale signals relating to user's holding assets and data constituting

In the scenario producing process, it is recommendable to produce a plurality of investment scenarios with different characteristics so that a user can select one investment scenario of them. It is preferable to set an animation character for each investment scenario so that the character can operate in accordance with management advice data to be an interface with the user in the management advising process. In this case, it is further possible to include a process of storing management performance records for a past prescribed period of each investment scenario and to present the management performance records as well as the animation character to the user in the management advising process. In this case of producing a plurality of investment scenarios, it is preferable to include a process of automatically collecting data concerning purchase and sale signals relating to an asset recommended according to the characteristics of each investment scenario and data constituting grounds for them to update the data base.

In the trading process of the asset management advice program, it is also possible for a user to select either the real mode in which to access the market to make transactions actually or the virtual mode in which not to access the market to make transactions virtually.

Other features and advantages of the invention will be more apparent from the following description in connection with the accompanying drawings.

Fig. 1 is a block diagram showing an example of an asset management advice system of the present invention; and

Fig. 2 is a block diagram showing another example of an asset management advice system of the present invention.

DETAILED DESCRIPTION OF PREFERRED EMBODIMENTS

Fig. 1 shows an example of a structure in which a host computer installed in an asset trading agent such as a securities company or an investment advisory company operates as a data processing means of an asset management advice system.

A user terminal of a personal computer (or a cellular phone) the user owns can communicate with a host of an asset trading agent such as a securities company or an investment advisory company from a dial-up adopter or a LAN adopter via a communications network such as the Internet. Data banks of the securities market, financial market and commodity market are also connected to the communications network, from which banks necessary information can be retrieved. Further, data banks of news agents, newspaper publishing companies and magazine publishing companies (not shown in the figure) are also connected to the network so that the user can access each kind of data such as the trends of the markets or the movement of the other markets.

The host of an asset trading agent such as a securities company or an investment advisory company has a data base storing purchase and sale signals that comprise quantitative and qualitative data relating to prices, the amounts of issuance/existence, the volumes of trading/purchase and sale and the sources of issuance/supply of securities and commodities constituting assets to be traded, quantitative and qualitative macro information data in the locations and the regions of transactions of the assets and data consisting of the above data processed and optimized in accordance with a prescribed calculation expression. The host accesses each data bank at least once per business day on the daily basis in principle to collect information, and automatically performs update of the data base. Further, with the update on the daily basis, data per week, month and year is also

002230"4E30E360

The user operates the terminal he owns to input his property information in the first place. The property information constitutes constraints such as user's preference with respect to asset management, capitals and the like, including the initial amount of management assets, the amount of an inflow of periodical cash flow (for example, the amount of a reserve of new savings per month), the cash holding rate (the percentage of cash in the total amount of assets, at which percentage or more cash is always held) and the extent of distributed investment (for example, the maximum number of brands in which the user will invest in the case of stocks). The property information input by the user is passed from the user terminal to the host via the communications means. The host receives it and produces a suitable investment scenario according to the property information. Namely, the host boots an investment judgement program suitable for the user.

In the case of this example, several kinds of investment scenarios are produced, each having individual characteristics. For example, a certain investment scenario is characterized in attaching importance on good bargains of stocks and purchasing brands meeting momentum conditions among conspicuous bargain brands overall. Another investment scenario is characterized in attaching importance on the growth prospects of companies and purchasing brands meeting momentum conditions among stocks with high growth prospects in profit. Still another investment scenario is characterized in calculating the degree of popularity of stocks from objective figures and purchasing brands meeting momentum conditions among brands

with high popularity. These characteristics are, however, not fixed and absolute. It is allowed for a user to change parameters within a certain range. For example, it is permissible to change to some extent how much to attach importance on good bargains or how much to attach importance on growth prospects or popularity in each investment scenario.

When these several kinds of investment scenarios with different characteristics are produced, the host presents them in the form of animation characters set for their respective scenarios to the user terminal. For example, a character like a gentleman is assigned to one investment scenario, a character other than a human being is for another investment scenario, and a character like a career woman is for still another investment scenario, thereby to distinguish them from each other and show them up on the display of the user terminal. At the same time, the host sends records of management performances for the past ten years of each character to the user terminal to help him judge the characteristics objectively.

The user selects one character suitable for his preference among the characters shown on the terminal and sends instructions to the host. On the selection of the investment scenario, the host refers to purchase and sale signals in the data base to send management advice data to advise what kind of brands are suitable at present and whether the brands should be sold or purchased in accordance with the selected investment scenario to the user terminal. Further, purchase and sale signals constituting grounds for the management advice data and data constituting grounds for the calculation of the purchase and sale signals are also presented to the user terminal, if necessary at that time.

At the user terminal, a transaction is proceeded in an interactive manner in which the character of the selected

09630834.080200

investment scenario talks and operates in accordance with the management advice data to present a management guide such as a recommended brand and the user performs an operation accordingly. At that time, the host operates, in accordance with user's selection, either in the real mode (connected to net trade) in which to access the terminal of the securities market, financial market or commodity market to actually send purchase and sale instructions or in the virtual mode (released from net trade) in which not to connect with the securities market, financial market or commodity market to make processing inside the host. In the real mode, the host sends profit and loss resulting from actual transactions to the user terminal and informs them through the character. In the virtual mode, the host simulates transaction situations inside the host based on the transition in price or trading volume at that day and informs the results to the user through the character. That is, virtual trade is performed realistically and asset management can be performed like a game accompanying no actual profit and loss.

Fig. 2 shows an example of a structure in which a user terminal a user owns serves as a data processing means of an asset management advice system. Namely, the user terminal plays the same role as the host computer in Fig. 1.

In this case, a server equipped with a data base is installed on the side of an asset trading agent such as a securities company or an investment advisory company to manage the data base. Specifically, the server accesses the data banks of the securities market, financial market and commodity market to collect data that constitutes grounds for calculating purchase and sale signals to update the data base, and also serves as the window for the user terminal to access the data base. The user terminal performs the same functions as the host computer shown in Fig. 1 except for accessing the data base of the asset

002090"4800960

trading agent such as a securities company or an investment advisory company through the server.

In accordance with the present invention, provided is not a data-presenting means for only presenting materials for judgement but an advice system in which asset management advice can be obtained in accordance with user's preference. This enables the user to utilize net trade as an asset management means more readily than before. Further, the virtual mode allows the user to simulate and experience a realistic asset transaction, being most suitable as an introduction to net trade.
